Summarizing and Anticipating the Next Decade with NRY, mtDNA and Autosomal DNA

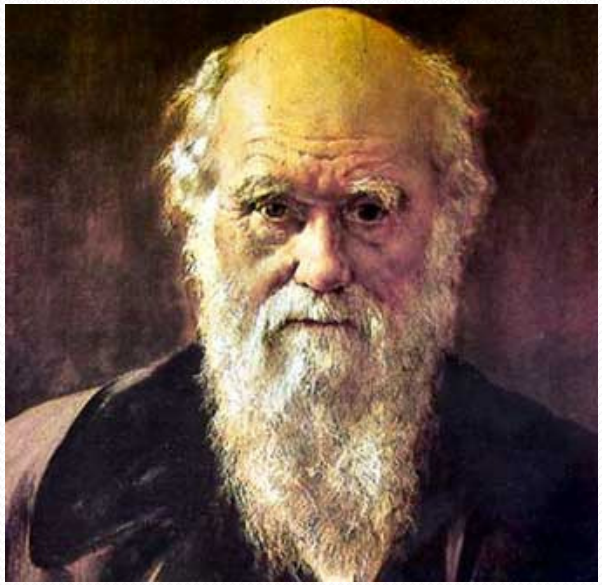
Doron M Behar
Family Tree DNA
6th International Conference on Genetic Genealogy

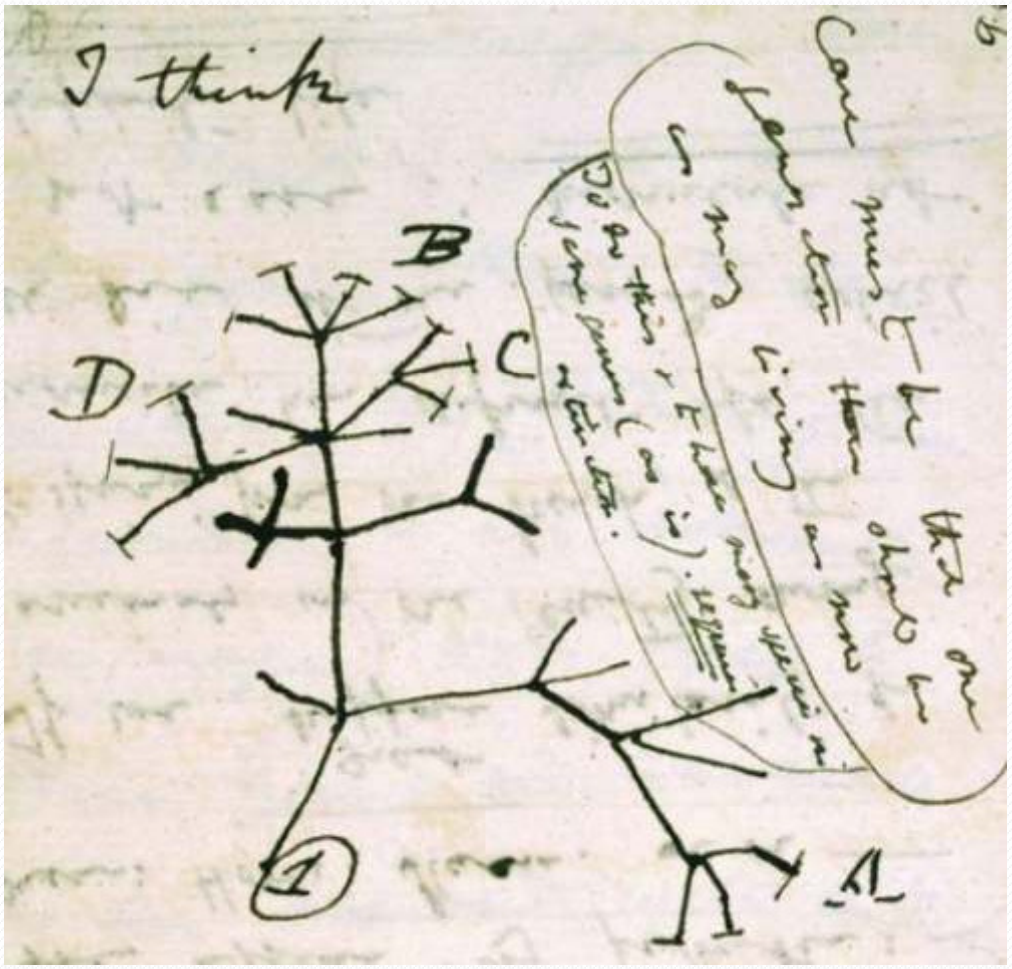
Historical landmarks(1/2)

- 1859 - Charles Robert Darwin: On the origin of species
- 1866 - Gregor Johann Mendel: Experiments on Plant Hybridization
- 1905 – William Bateson: Coin the term “genetics”
- 1910 - Thomas Hunt Morgan: Genes are on chromosomes
- 1944 - Oswald Theodore Avery, Colin McLeod and Maclyn McCarty - identified the DNA molecule

“I think”

Darwin's first diagram of an evolutionary tree from his 'First Notebook on Transmutation of Species' (1837)."





Hominini Tribe

Kingdom:	Animalia
Phylum:	Chordata
Class:	Mammalia
Order:	Primates
Family:	Hominidae
Subfamily:	Homininae
Tribe:	Hominini
Genus:	Homo
Species:	H. sapiens

Historical landmarks(2/2)

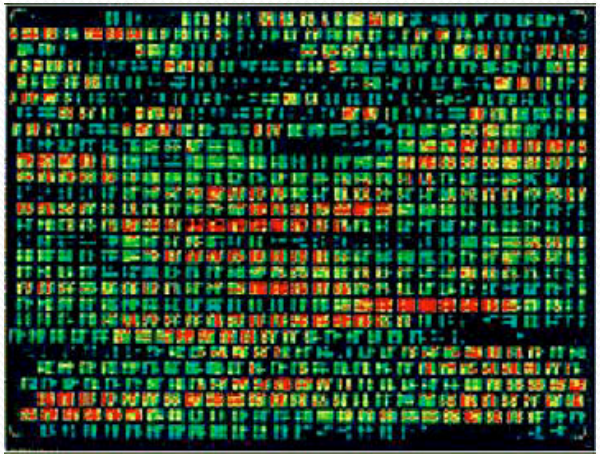
- 1953 –Rosalind Franklin, James D. Watson, Fancis Crick: the double helix
- 1977 – Frederick Sanger: DNA sequencing
- 1983 – Kary Banks Mullis: Polymerase Chain Reaction
- 2003 – Human Genome Project and Celera Genomics: the human genome
- 2005 – HapMap project
- 2008 - 1000 Genomes Project

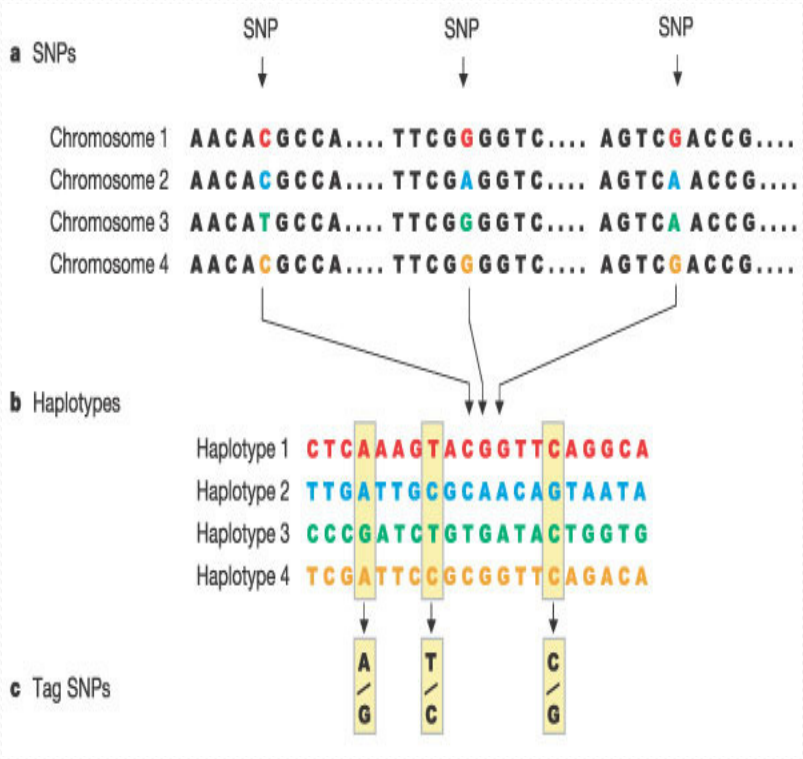
Human Genome Project

- A 13 years old project completed in 2003:
  - *identify* all the 20,000-25,000 human genes
  - *determine* the sequences of human DNA
  - *store* this information in databases,
  - *improve* tools for data analysis
  - *transfer* related technologies to the private sector
  - *address* the ethical, legal, and social issues
- 200 separate principal investigators for 18 countries
- Reported to have cost $3 billion

HapMap project

- DNA sequences differ in every 1,200 base pairs
- Approximately 10 million SNPs estimated to occur commonly in the human genome
- The number of tag SNPs are only 600,000 bp
- Genotype only these SNPs to locate genes involved in medically important traits.





1,000 Genomes Project

Genetic epidemiology literature in Europe—an overview

R. Ádány, Z. Pocsai

mtDNA – The first steps

RFLP based analysis

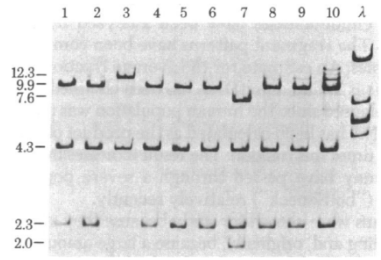

FIG. 1. A 1.2% agarose gel electrophoresis of *Hpa* I digests of human mtDNA samples 1–10. The band patterns of samples 3 and 7 differ from those of the other samples. The DNA fragment sizes, shown on the left in bp × 10^{-3}, were estimated from a calibration curve using *Eco*RI-digested λ DNA (above) and *Hin*dIII-digested PM2 DNA (not shown) as size standards. Faint bands are due to incomplete digestion.

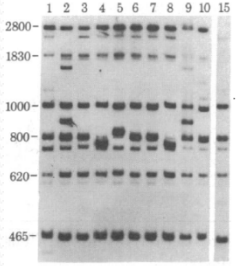

FIG. 2. A 3.5% polyacrylamide gel of *Mbo* I digests of human mtDNA samples 1–10 and 15. All atypical fragments observed were ≥450 bp, hence the portion of the gel containing smaller fragments is not shown. The band pattern shown by samples 3, 6, and 7 was typical for the majority of the 21 samples analyzed. Samples 2 and 9 show identical atypical patterns, as do samples 4 and 8. The DNA fragment sizes, in bp, are shown on the left. The faint bands are completely digested fragments that, because of the labeling method, do not label well.

Table 3. Distribution of restriction endonuclease polymorphisms in mtDNAs from 21 humans

Endonuclease	Morph in sample																				
	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21
A. *Bam*HI		2							2												
B. *Hpa* I			2				3								3						
C. *Kpn* I										2											
D. *Hin*cII			2																		
E. *Alu* I	2			3, 4	5, 6	2	7	3		6	2		2		7, 8			9	2		
F. *Hae* III				2	3			2		3	3	3, 4		5		4	6, 7	3		8	9
G. *Hha* I	2		3						3		4										5
H. *Hin*fI				2	3		3, 4, 5	2		3				3, 6, 7	3, 4		3	8		9	3, 10
I. *Hpa* II		2, 3					4						5								
J. *Mbo* I	2	3		4	5			4	3	6					7						
K. *Taq* I							2, 3							4	5				6		7

The samples were monomorphic for the following enzymes: *Eco*RI, *Hin*dIII, *Xba* I, *Pst* I, *Pvu* II, *Sac* I, and *Xho* I (see ref. 10 and text). The characteristics of the numbered polymorphisms are as explained in Table 2 and the text. A blank indicates morph no. 1.

Communicated by Ruth Sager, March 27, 1980

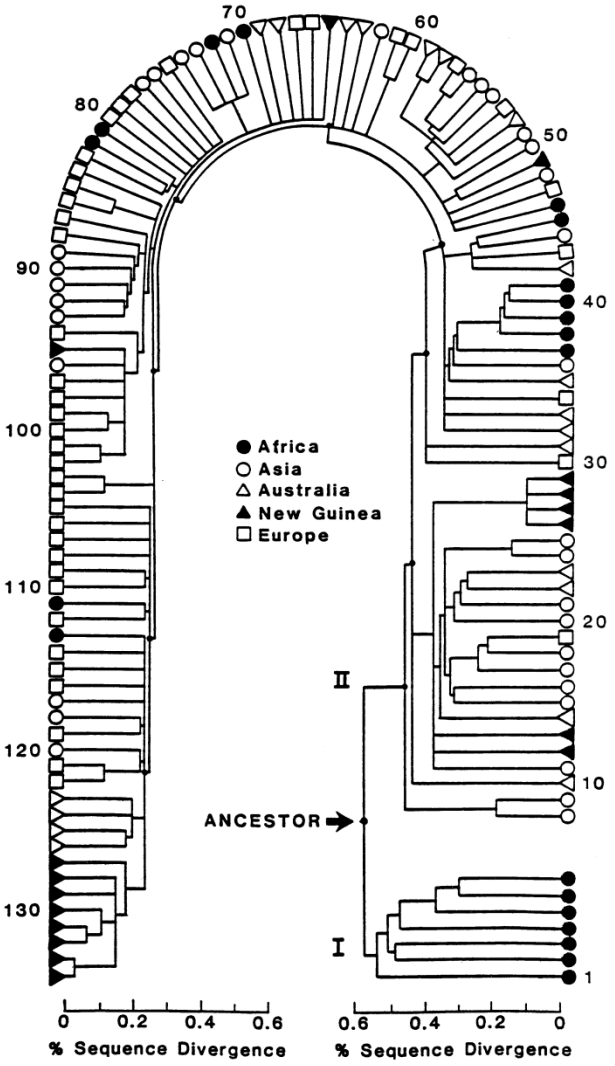
African Eve

Mitochondrial DNA and human evolution

Rebecca L. Cann*, Mark Stoneking & Allan C. Wilson
Department of Biochemistry, University of California, Berkeley, California 94720, USA
* Present address: Department of Genetics, University of Hawaii, Honolulu, Hawaii 96822.

Nature **325**, 31 - 36 (01 January 1987)

Mitochondrial DNAs from 147 people, drawn from five geographic populations have been analysed by restriction mapping. All these mitochondrial DNAs stem from one woman who is postulated to have lived about 200,000 years ago, probably in Africa. All the populations examined except the African population have multiple origins, implying that each area was colonised repeatedly.



Using the HVSI

Pygmies and Bantus

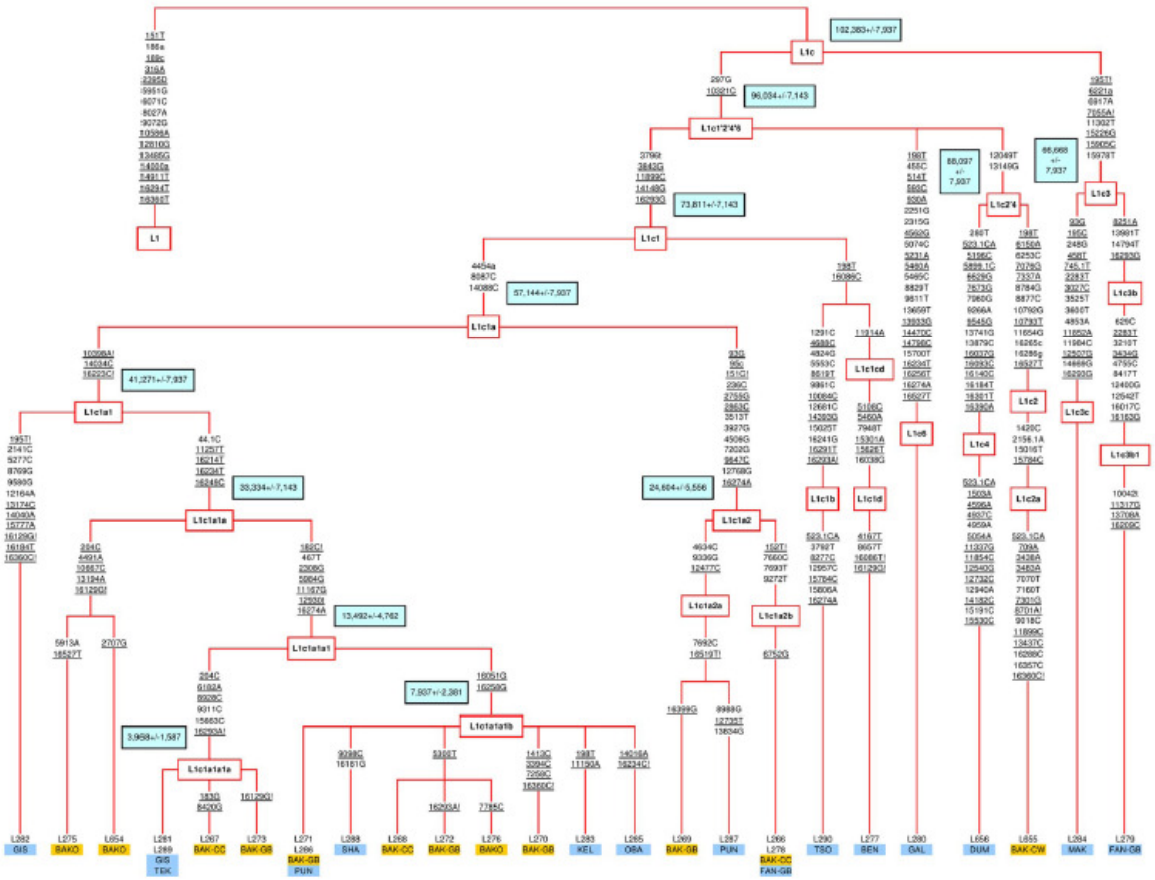

Fig. 1. Phylogenetic tree of complete mtDNA sequences belonging to haplogroup L1c. The tree is rooted on Hg L1 and shows subhaplogroup affiliations. Mutations are shown on the branches. Transitions are labeled in uppercase letters, transversions are indicated in lowercase letters, deletions are indicated by a "d" after the deleted nucleotide position, and insertions are indicated by a dot, followed by the number and type of inserted nucleotides. Underlined nucleotide positions occur at least twice in the tree. The exclamation mark (!) at the end of a nucleotide position denotes a reversion to the ancestral state in the relative pathway from the rCRS (36). Individuals highlighted in orange correspond to PHG and those in blue to Bantu-speaking AGR. Population codes for each individual are as in Table 1. Coalescence age estimates for the main subhaplogroups are also reported.

Maternal traces of deep common ancestry and asymmetric gene flow between Pygmy hunter–gatherers and Bantu-speaking farmers

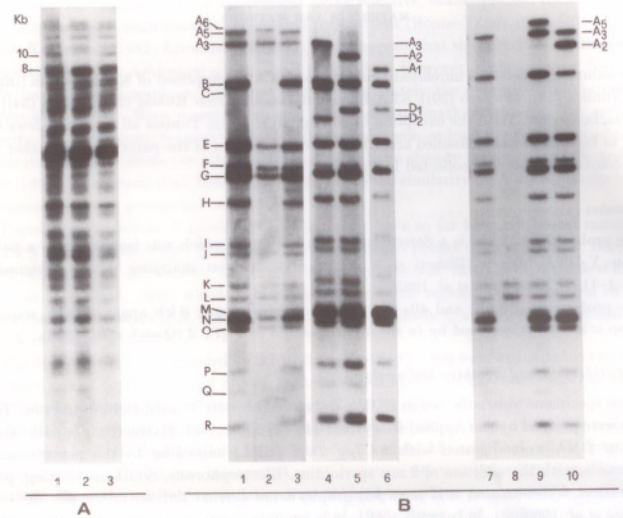

Fig. 1. Electrophoretic patterns of human male DNAs digested with *Taq*I and hybridized: (*A*) by p12f2 (allelic fragments of 10 and 8 kb). The 10 kb band in lane 1 and 3 is not present in lane 2 where the 8 kb fragment, independent of this polymorphism, appears to be reinforced. (*B*) by p49a,f. With the exception of K and L, which are also present in female patterns (lane 8), all of the numerous bands identified by these probes are Y-specific (Ngo *et al.* 1986). Lanes 1, 3 and 9, haplotype 49 ($A_{3,5}C_6D_6F_1I_1$); lane 2, haplotype 62 ($A_{3,6}C_6D_6F_1I_6$, with the absence of the BHPR bands); lane 4, haplotype 15 ($A_3C_1D_2F_1I_1$); lane 5, haplotype 8 ($A_2C_6D_1F_1I_1$); lane 6, haplotype 42 ($A_1C_6D_1F_1I_1$); lane 7, haplotype 11 ($A_2C_6D_6F_1I_1$); lane 10, haplotype 52 ($A_{2,3}CO_6D_6F_1I_1$).

In conclusion, the analysis of these Y-specific polymorphisms has given further impressive support to the common origin of Sephardim and Ashkenazim, has indicated a low contribution of foreign Y-chromosomes to the Ashkenazi gene pool but has also shown a striking similarity between Jews and people from the same land of origin. Is this surprising? Didn't Ishmael and Isaac each receive a copy of Abraham's Y-chromosome?

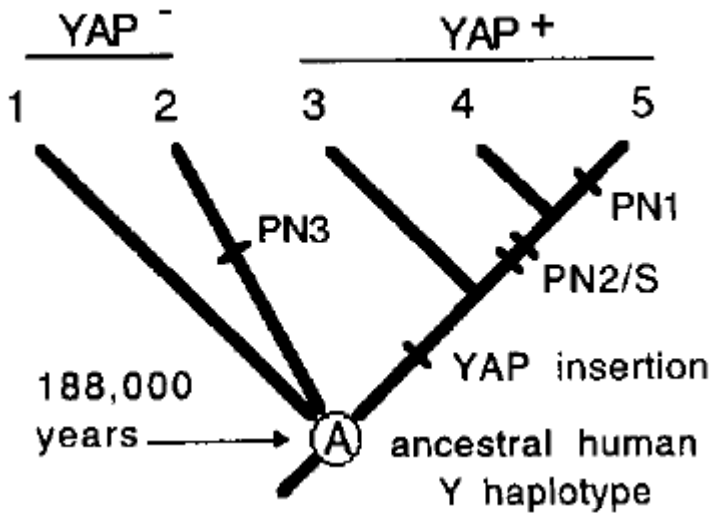
Adam

A recent common ancestry for human Y chromosomes

Michael F. Hammer

Laboratory of Molecular Systematics and Evolution, Biosciences West, University of Arizona, Tucson, Arizona 85721, USA

NATURE · VOL 378 · 23 NOVEMBER 1995



distribution[11]). This age agrees with estimates of the ancestral human mtDNA molecule[12,13]. An implication of these results (Fig. 2) is that the current distribution of Y chromosomes carrying the YAP element[14,15] reflects migrations of male *H. sapiens* from Africa to Europe and Japan.

A coherent picture now emerges that places both our common ancestral Y chromosome and mitochondrial DNA molecule in the late middle Pleistocene only slightly before the hypothesized

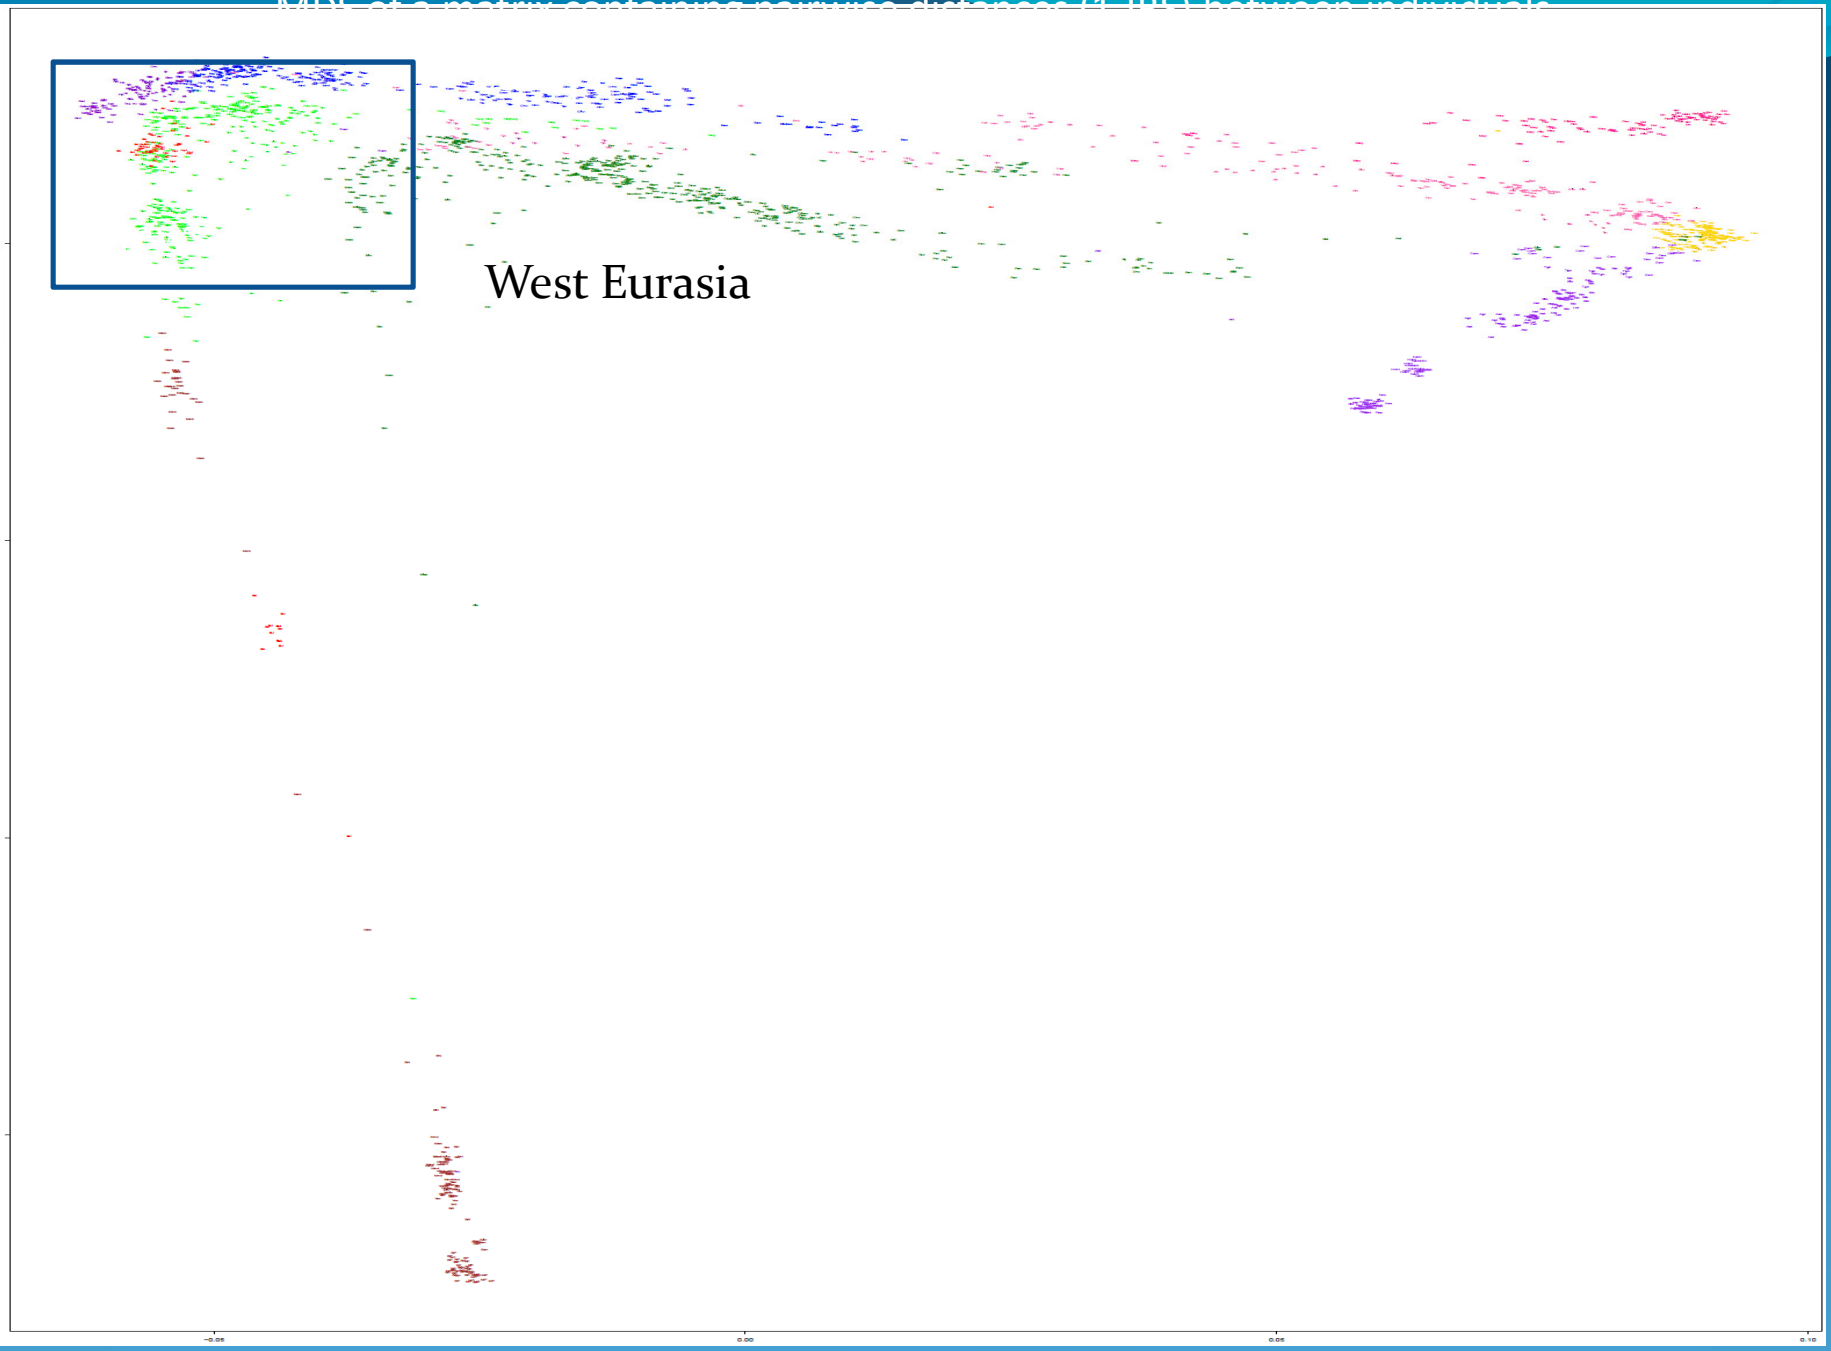
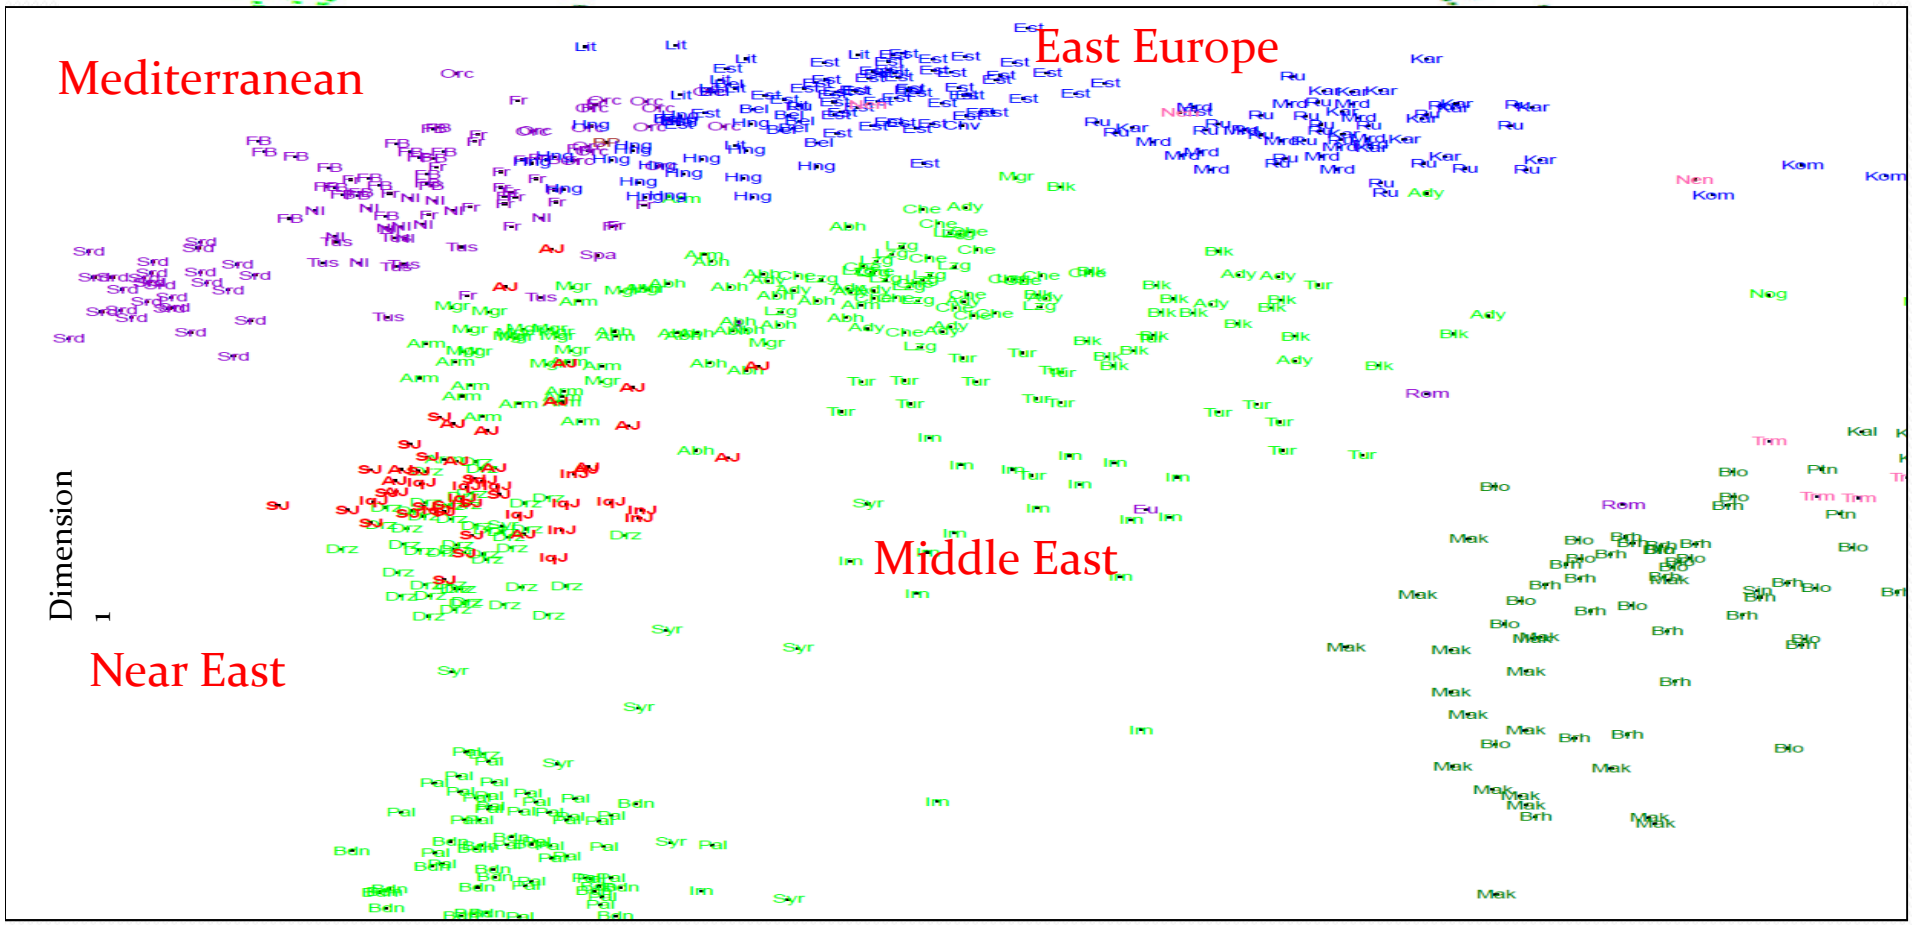
Principal Components Analysis



West Eurasia
Dimension 2

MDS of a matrix containing pairwise distances (1-IBS) between individuals



The Cape Mixed Ancestry population

- Commonly self identified as South African “Cape Coloured”
- Established later than 1652
- Make up 9% of the South African population
- Historical records suggest the fusion of indigenous Khoi and San, tribal Bantu-speaking populations, European settlers and slaves’ descendants from Java, India, Mozambique and Madagascar

Cape, Biparental level

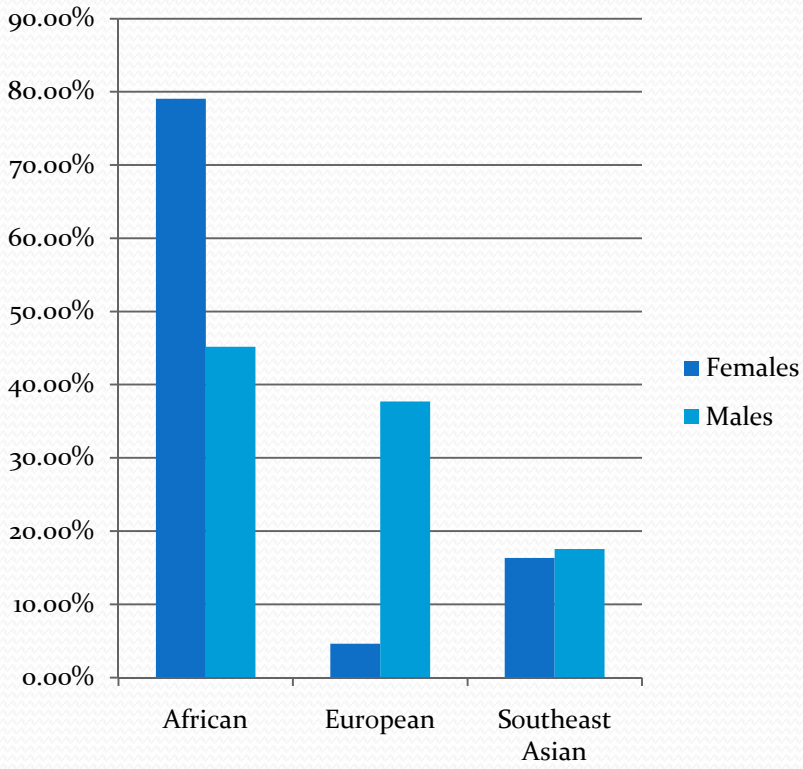
The American Journal of Human Genetics *86*, 611–620, April 9, 2010

Sexual asymmetry



Biparental vs Uniparental

- Biparental markers contain far larger amount of variation as well as larger population effective size
- Uniparental markers contain far less amount of variation but are superior with respect to the ability to:
  - draw solid hierarchical phylogenies.
  - trace migrations patterns
  - estimate coalescence and expansion ages
  - infer sexually asymmetric parental demographic histories

What have we achieved?

1	2	3	4	5
Critical mass of uniparental and biparental markers	Critical mass of samples	A combined NRY, mtDNA and autosomal approach	The “big picture” is resolved	**Now we need the details!**

The Human Genome Promise

- Molecular medicine
- Energy sources and environmental applications
- Risk assessment
- Bioarchaeology, anthropology, evolution, and human migration
- DNA forensics (identification)
- Agriculture, livestock breeding, and bioprocessing

Molecular Medicine

- *Improved diagnosis of disease*
- *Earlier detection of genetic predispositions to disease*
- *Rational drug design*
- *Gene therapy and control systems for drugs*
- *Pharmacogenomics "custom drugs"*

The Race

- The **Archon X Prize** for Genomics:

  The $10 million prize (US), donated by diamond prospector Stewart Blusson, is to be awarded to "the first Team that can build a device and use it to sequence 100 human genomes within 10 days or less, with an accuracy of no more than one error in every 100,000 bases sequenced, with sequences accurately covering at least 98% of the genome, and at a recurring cost of no more than $10,000 (US) per genome."

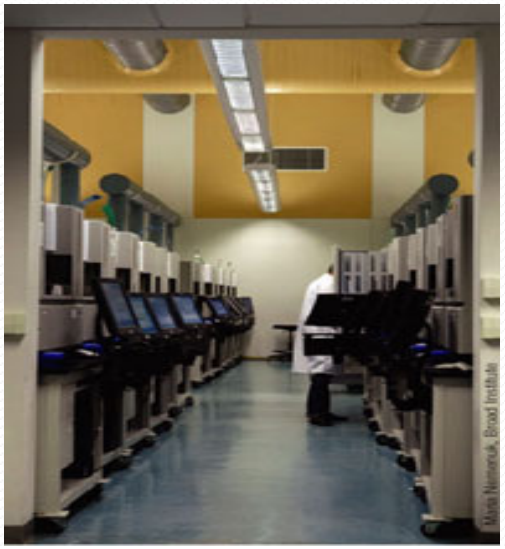
Answering the challenge

- Illumina
- Sequenom
- 454 Life Sciences
- Pacific Biosciences
- Intelligent Bio-Systems
- Genome Corp
- ION Torrent Systems
- Helicos Biosciences
- Compete genomics
- Halcyon Molecular
- IBM
- GE Global

Sequencing

Conventional

- Sanger based technology
- A 30 years old monopoly
- 600-1000 bp per read
- Reaction time is a few hours
- 10,000,000 reactions to sequence the genome



Next generation

- Developed in 2005 by 454 Life Sciences
- A throughput equivalent to 50 Applied Biosystem's 3730XL capillary sequencers at about one-sixth of the cost

Full Genome Sequencing prices

- Conventional sequencing - $10M
- January 2009, Knome complete.Com - $68,500
- June 2009,Illumina - $48,000
- August 2009, Helicos - <$50,000
- November 2009, Complete Genomics - $1,700

Claims

- April 2009, Complete Genomics: “plan to be able to sequence one million full genomes *per year* by 2013”
- June 2009, Illumina: “during the next five years, perhaps markedly sooner, the price point for full genome sequencing will fall from $48,000 to under $1,000”.
- August 2009, Pacific Biosciences: “will sequence 10,000 full genomes by the end of 2010”.
- August 2009, GE Global Research: “is also now in the race to commercialize full genome sequencing as they are currently working on creating a service that will deliver a full genome for $1,000 or less”.
- September 2009, Halcyon Molecular: “will be able to provide full genome sequencing in under 10 minutes for less than $100 per genome”.
- October 2009, IBM: “they were also in the heated race to provide full genome sequencing for under $1,000, with their ultimate goal being able to provide their service for $100 per genome”.

Common Uses of DNA Products

- Ancestry:
  - Parental tracing: Anthropological, Genealogical
  - Admixture analysis
- Forensic:
  - Paternity testing
  - Direct identification of a subject
  - Predicting traits
- Personalized Medicine:
  - Mendelian disorders
  - Strong traits
  - Weak associated traits

The Changed Paradigm

Healthcare providers

- Mendelian disorders
- Paternity testing
- Direct identification of a subject

Direct-to-consumer

- Paternal tracing
- Admixture analysis
- Weak associated traits
- Strong traits
- Mendelian disorders
- Paternity testing

The major players

Industry

- Elimination of technological barriers
- Towards a $1,000 personal full genome sequence
- A thriving direct-to-consumer market

Institutional

- Ethical, Legal and Social issues are under debate
- Minimal penetration of the knowledge to clinical standards of care
- No appropriate education of healthcare providers
- Bioinformatics tools are lacking

Conclusions

- It is possible that in this decade it will be easier, cheaper, more accurate and more informative to genotype genes over specific mutations.
- It is likely that the goal of $1,000 per full genome sequence will be met in this decade.
- The ethical, legal and social issues allowing the *transfer of the information to the public* will be clarified, legislated and approved.

Thank you!
